Bonus Effort…

P1. Compute 2D intersection points of lines

AxB with Cx, AxD with BxC, DxE with BxF, and AxF with ExC

on using selected corner locations in the original imagery and the corresponding locations in the generated warped imagery

P2. Are they collinear? How would you test that?

P2A. If not, WHY? How can you make them collinear?

P2B. If yes, compute the cross ratio for the four points in both images. What is the value you expect? How can you enforce such value?
